### DIFFERENTIAL EQUATIONS

#### INTRODUCTION

During the past three decades the development of non-linear analysis, dynamical systems and their applications to Science and Engineering has stimulated renewed enthusiasm for the theory of Ordinary Differential Equations (ODE).

An Ordinary Differential Equation is an equation containing a function of one independent variable and its derivatives. Differential equations have wide application in various engineering and science discipline. In general, modeling variations of a physical quantity, such as temperature, pressure, displacement, velocity, stress, strain or concentration of pollutant with the change of time 't' or location, or both would require differential equation. The study of differential equation began in 1675, when Gottfried Willhelm Von Leibniz (1646 - 1716) wrote the equation.

$$\int x \, dt = \frac{x^2}{2}$$

The search for general methods of integrating differential equations began when Isaac Newton (1646 - 1727) classified first order Differential equations

$$(i) \quad \frac{dy}{dx} = f(x)$$

$$(ii) \quad \frac{dy}{dx} = f(x, y)$$

$$(iii) \quad x \frac{\partial y}{\partial x} + y \frac{\partial y}{\partial x} = u$$

The first two classes contain only ordinary derivatives of one dependent variable, with respect to single independent variable, and are known today as Differential Equation and third is partial differential equation.

A simple example is Newton's second law of motion, the relationship between the displacement 'x' and time 't' of the object under the force F which leads to the differential equation is

$$m \left( \frac{d^2 x(t)}{dt^2} \right) = F[x(t)] \quad \dots(1)$$

for the motion of a particle with constant mass 'm'. In general, F depends on the position x(t) on the particle at time 't' and so the unknown function x(t) appears on both sides of the differential equations as in the notation  $F[x(t)]$ .

### Linear Differential equations with Constant Coefficients

The general form on  $n^{\text{th}}$  order linear differential equation with constant coefficient is

$$a_0 \frac{d^n y}{dx^n} + a_1 \frac{d^{n-1} y}{dx^{n-1}} + a_2 \frac{d^{n-2} y}{dx^{n-2}} + \dots + a_{n-1} \frac{dy}{dx} + a_n y = X \quad \dots(2)$$

where  $a_0 \neq 0$ ,  $a_1, a_2, \dots, a_n$  are constants and 'X' is a function of  $x$ .

put  $D = \frac{d}{dx}, D^2 = \frac{d^2}{dx^2}, \dots, D^n = \frac{d^n}{dx^n}$

Eqn (2) becomes

$$(a_0 D^n + a_1 D^{n-1} + a_2 D^{n-2} + \dots + a_{n-1} D + a_n) y = X \quad \dots(3)$$

The general solution of (3) is

$y = \text{Complementary Function} + \text{Particular Integral}$

i.e.,  $y = \text{C.F.} + \text{P.I.}$

### To find the Complementary Function

The Auxiliary Equation of (3) is obtained by putting  $D = m$  and  $X = 0$ .

$\therefore$  The Auxiliary eqn is

$$a_0 m^n + a_1 m^{n-1} + \dots + a_n = 0 \quad \dots(4)$$

Solving equation (4), we get 'n' roots for 'm'. Say  $m_1, m_2, \dots, m_n$ .

**Case (i):** If all the roots  $m_1, m_2, \dots, m_n$  are real and different, then the complementary function,

$$C.F. = Ae^{m_1 x} + Be^{m_2 x} + Ce^{m_3 x} + \dots$$

**Case (ii):** If any two roots are equal say  $m_1 = m_2 = m$  (say), then the complementary function is given by

$$C.F. = (Ax + B)e^{mx} \text{ (or) } (A + Bx)e^{mx}$$

**Case (iii):** If any three roots are equal say  $m_1 = m_2 = m_3 = m$ , then the complementary function is given by

$$C.F. = (Ax^2 + Bx + C)e^{mx} \text{ (or) } (A + Bx + Cx^2)e^{mx}$$

**Case (iv):** If the roots are imaginary of the form  $(\alpha \pm i\beta)$  then the complementary function is

$$C.F. = e^{\alpha x} [A \cos \beta x + B \sin \beta x]$$

### To find particular Integral

When the R.H.S. of the given differential equation is zero, we need not find particular Integral. When R.H.S. of a given differential equation is a function of  $x$  say  $e^{ax}$ ,  $\sin ax$  or  $\cos ax$ ,  $x^n$ ,  $e^{ax} f(x)$ ,  $x f(x)$ , we have to find particular Integral.

**Case (i):** If  $f(x) = e^{ax}$ , then  $P.I. = \frac{1}{F(D)} e^{ax}$  Replace  $D$  by  $a$  in  $F(D)$ , provided  $F(D) \neq 0$ .

If  $F(a) = 0$ , then  $P.I. = \frac{x}{F'(D)} e^{ax}$ , provided  $F'(a) \neq 0$ .

If  $F'(a) = 0$ , then  $P.I. = \frac{x^2}{F''(D)} e^{ax}$ , provided  $F''(a) \neq 0$  and so on.

**Case (ii):** If  $f(x) = \sin ax$  or  $\cos ax$  then

$$P.I. = \frac{1}{F(D)} \sin ax \text{ or } \cos ax$$

Replace  $D^2$  by  $-a^2$  in  $F(D)$ , provided  $F(D) \neq 0$ .

If  $F(D) = 0$ , when we replace  $D^2$  by  $-a^2$  then

$$P.I. = \frac{x}{F'(D)} \sin ax \text{ (or) } \cos ax$$

Again replace  $D^2$  by  $-a^2$  in  $F(D)$  provided  $F'(D) \neq 0$ , then  $P.I. = \frac{x^2}{F''(D)} \sin ax$  (or)  $\cos ax$

and the process may be repeated if  $F(D) = 0$  and so on.

**Case (iii):** If  $f(x) = x^n$ , then  $P.I. = \frac{1}{F(D)} x^n$

$$= [F(D)]^{-1} x^n$$

Expand  $[F(D)]^{-1}$  by using Binomial theorem and then operate on  $x^n$ .

**Case (iv):** If  $f(x) = e^{ax} X$ , where  $X$  is  $\sin ax$  (or)  $\cos ax$ , then

$$P.I. = \frac{1}{F(D)} e^{ax} X = e^{ax} \frac{1}{F(D+a)} X$$

Here  $\frac{1}{F(D+a)} X$  can be evaluated by using anyone of the first three types.

**Case (v):** If  $f(x) = x^n \sin ax$  or  $x^n \cos ax$ , then

$$P.I. = \frac{1}{F(D)} x^n \sin ax \text{ (or) } x^n \cos ax$$

$$\text{Now, } \frac{1}{F(D)} x^n (\cos ax + i \sin ax)$$

$$= \frac{1}{F(D)} x^n e^{iax}$$

$$= e^{iax} \frac{1}{F(D+ia)} x^n$$

$$\therefore \frac{1}{F(D)} x^n \sin ax = \text{Imaginary part of } e^{iax} \frac{1}{F(D+ia)} x^n$$

$$\frac{1}{F(D)} x^n \cos ax = \text{Real part of } e^{iax} \frac{1}{F(D+ia)} x^n$$

1. Solve:  $(D^2 + 5D + 4)Y = e^{-x} \sin 2x$

Solution: Given,  $(D^2 + 5D + 4)y = e^{-x} \sin 2x$

(i) To find C.F.

$$(D^2 + 5D + 4)y = 0$$

The auxiliary equation is

$$m^2 + 5m + 4 = 0$$

$$(m + 1)(m + 4) = 0$$

$$m + 1 = 0, m + 4 = 0$$

$$m = -1, m = -4$$

The roots are real and distinct

$$\therefore \text{C.F} = Ae^{m_1 x} + Be^{m_2 x}$$

$$= Ae^{-x} + Be^{-4x}$$

(ii) To find P.I.

$$\text{P.I} = \frac{1}{D^2 + 5D + 4} e^{-x} \sin 2x$$

Here,  $a = -1$  and  $b = 2$

Replace  $D$  by  $D + a = D - 1$

$$\text{P.I} = e^{-x} \frac{1}{(D-1)^2 + 5(D-1) + 4} \sin 2x$$

$$= e^{-x} \frac{1}{D^2 - 2D + 1 + 5D - 5 + 4} \sin 2x$$

$$= e^{-x} \frac{1}{D^2 + 5D} \sin 2x$$

## LINEAR DIFFERENTIAL EQUATIONS WITH VARIABLES CO-EFFICIENTS

### *I - Cauchy Euler Type*

An equation of the form

$$a_0 x^n \frac{d^n y}{dx^n} + a_1 x^{n-1} \frac{d^{n-1} y}{dx^{n-1}} + \dots + a_{n-1} x \frac{dy}{dx} + a_n y = X \quad \dots(1)$$

Where  $a_0, a_1, \dots, a_n$  are constants and  $X$  is a function of  $x$  is called Euler's homogeneous linear differential equation.

Equation (1) can be reduced to constant co-efficient by means of transformation

$$x = e^z \text{ (or) } z = \log x$$

$$\begin{aligned} \frac{dy}{dx} &= \frac{dy}{dz} \cdot \frac{dz}{dx} \\ &= \frac{1}{x} \frac{dy}{dz} [\because x = e^z \Rightarrow z = \log x] \end{aligned}$$

$$x \frac{dy}{dx} = D'y \quad \text{where } D' = d/dz \quad (2)$$

Now

$$\begin{aligned} \frac{d^2 y}{dx^2} &= \frac{d}{dx} \left( \frac{dy}{dx} \right) = \frac{d}{dx} \left( \frac{1}{x} \frac{dy}{dz} \right) \\ &= \frac{1}{x} \frac{d}{dx} \left( \frac{dy}{dz} \right) + \frac{dy}{dz} \frac{d}{dx} \left( \frac{1}{x} \right) \\ &= \frac{1}{x} \frac{d}{dz} \left( \frac{dy}{dz} \right) \frac{dz}{dx} + \frac{dy}{dz} \left( \frac{-1}{x^2} \right) \\ &= \frac{1}{x} \frac{d^2 y}{dz^2} - \frac{1}{x^2} \frac{dy}{dz} \end{aligned}$$

$$\frac{d^2 y}{dx^2} = \frac{1}{x^2} \frac{d^2 y}{dz^2} - \frac{1}{x^2} \frac{dy}{dz}$$

$$\begin{aligned} \therefore x^2 \frac{d^2 y}{dx^2} &= \frac{d^2 y}{dz^2} - \frac{dy}{dz} \\ &= (D'^2 - D') y \quad \text{where } D' = d/dz \end{aligned}$$

$$x^2 \frac{d^2 y}{dx^2} = D'(D' - 1)y \quad \dots(3)$$

$$\text{Similarly } x^3 \frac{d^3 y}{dx^3} = D'(D' - 1)(D' - 2)y \quad \dots(4)$$

and so on. Substituting (2), (3), (4) and so on in (1), differential equation of variables co-efficients reduced to constant co-efficients and can be solved by any one of the known methods.

## *II – Legendre's Type*

An equation of the form

$$a_0(ax+b)^n \frac{d^n y}{dx^n} + a_1(ax+b)^{n-1} \frac{d^{n-1} y}{dx^{n-1}} + \dots + a_n y = X \quad \dots(1)$$

where  $a_0, a_1, \dots, a_n$  are constants and  $X$  is a function of  $x$  is called Legendre's linear differential equation.

Equation (1) can be reduced to linear differential equation with constant co-efficient by the substitution.

$$ax + b = e^z \Rightarrow z = \log(ax + b)$$

$$(ax + b) \frac{dy}{dx} = a \frac{dy}{dz}$$

$$(ax + b) D = aD', \quad \text{where } D' = d / dz$$

Similarly  $(ax + b)^2 D^2 = a^2 D (D' - 1)$  and so on.

### **Simultaneous linear Differential Equations with constant co-efficients**

Simultaneous linear Differential Equations:

The system of differential equations which consist of one independent and two or more dependent variables.

To solve such system completely, we must have as many simultaneous equations as the number of dependent variables.

Here we consider only the 1st order simultaneous linear differential equations.

Let  $x, y$  be the two dependent variables and ' $t$ ' be the independent variable, then consider the system like

$$f_1(D)x + g_1(D)y = \Phi(t) \quad \dots(1)$$

$$f_2(D)x + g_2(D)y = \Phi(t) \quad \dots(2)$$

$$D = \frac{d}{dt}$$

Where  $f_1, f_2, g_1, g_2$  are polynomials in  $D$ .

### **Methods to solve the simultaneous equations**

Solving simultaneous differential equation is based on the process of elimination of the variables which is applied in solving the simple algebraic equations.

### Method 1

The method of solution is to eliminate the dependent variables  $x$  or  $y$  between the two given equations. First getting an equation in the dependent variable and then solve the equations by the methods as used already.

After getting the solution either for  $x$  or  $y$ , substitute the solution either in (1) or in (2) to get the solution for the other dependent variable.

*Note (1)*

The number of arbitrary constants in the solution of the system

$$f_1(D)x + g_1(D)y = \phi_1(t)$$

$$f_2(D)x + g_2(D)y = \phi_2(t)$$

is equal to the degree of  $D$  in the determinant  $\begin{vmatrix} f_1(D) & g_1(D) \\ f_2(D) & g_2(D) \end{vmatrix}$  (i.e.) The number of arbitrary constants in the solution of the system is equal to the number of dependent variables appeared in the system.

### Example:

Consider the system  $\frac{dx}{dt} + y = \sin t$ ;  $\frac{dy}{dt} + x = \cos t$ . Here the number of arbitrary constants is equal to the number of dependent variables in the system

Let  $D = \frac{d}{dt}$ , then the above system is

$$Dx + y = \sin t \quad \dots(1)$$

$$Dy + x = \cos t \quad \dots(2)$$

$$\text{Now } \begin{vmatrix} f_1(D) & g_1(D) \\ f_2(D) & g_2(D) \end{vmatrix} = \begin{vmatrix} D & 0 \\ 0 & D \end{vmatrix} = D^2, \text{ Here the degree is 2}$$

∴ We have two arbitrary constants in the solution of the system.

## Method 2

Elimination of  $x$  in the equations (1) and (2) gives the solution of  $y$ , in which we have two arbitrary constants.

Likewise elimination of  $y$  in the equations (1) and (2) gives the solution.

But according to the rule (in Note), we must have only two arbitrary constants. Therefore we can write the relation between the arbitrary constants. (i.e) one constant can be expressed in terms of other.

*Note (2)*

Also, we can eliminate first  $y$  and then using  $y$  we may find out the solution of  $x$ .

## Problems

1. Solve:  $\frac{dx}{dt} + y - 1 = \sin t$ ;  $\frac{dy}{dt} + x = \cos t$  (S.U 2006)

Solution: Given  $\frac{dx}{dt} + y - 1 = \sin t$ ;  $\frac{dy}{dt} + x = \cos t$

Let  $D = \frac{d}{dt}$ , then the above equations are  $Dx + y - 1 = \sin t$

(i.e)  $Dx + y = \sin t + 1$  ... (1)

And  $Dy + x = \cos t$  ... (2)

First we can eliminate  $x$  from (1) and (2)

$(2) \times D \Rightarrow D^2 y + Dx = D(\cos t) = -\sin t$  ... (3)

(i.e)  $Dx + D^2 y = -\sin t$

$$\begin{array}{r} \cancel{Dx} + y = \sin t + 1 \\ (1) - (3) \quad \cancel{Dx} + D^2 y = -\sin t \\ \hline (-D^2 + 1)y = 2 \sin t + 1 \end{array}$$

$$(i.e) -(D^2 - 1)y = 2 \sin t + 1$$

(i.e)  $(D^2 - 1)y = -2 \sin t - 1$  which is 2<sup>nd</sup> order differential equation in  $y$  with constant coefficients.

$\therefore$  The solution of  $y(t) = C.F. + P.I.$

Now the Auxiliary equation is

$$m^2 - 1 = 0$$

$$(i.e) m^2 = 1$$

$$\Rightarrow m = \pm 1$$

$$\therefore C.F. = Ae^t + Be^{-t}$$

$$\begin{aligned} P.I. &= \frac{1}{D^2 - 1}(-2 \sin t - 1) \\ &= \frac{1}{D^2 - 1}(-2 \sin t) - \frac{1}{D^2 - 1}e^{0t} \\ &= \frac{-2}{-1 - 1} \sin t - \frac{1}{0 - 1}e^{0t} \\ &= \frac{-2}{-2} \sin t + \frac{1}{1}e^{0t} \\ &= \sin t + 1 \end{aligned}$$

$$\therefore y = Ae^t + Be^{-t} + \sin t + 1$$

To find the solution of  $x$ , first we can find  $Dy$ .

$$\begin{aligned} Dy &= D[Ae^t + Be^{-t} + \sin t + 1] \\ &= Ae^t - Be^{-t} + \cos t \end{aligned}$$

Consider the equation (2)

$$Dy + x = \cos t$$

$$\Rightarrow x = \cos t - Dy$$

$$x = \cos t - (Ae^t - Be^t + \cos t)$$

$$= \cancel{\cos t} - Ae^t + Be^t - \cancel{\cos t}$$

$$x = Be^{-t} - Ae^t$$

∴ The solutions are

$$x = Be^{-t} - Ae^t$$

$$y = Ae^{-t} + Be^t + \sin t + 1$$

where  $A$  and  $B$  are arbitrary constants.

2. Solve  $\frac{dx}{dt} + y = \sin t$ ;  $\frac{dy}{dt} + x = \cos t$  where  $x(0) = 2$  and  $y(0) = 5$  (S.U 2007)

Solution: Given  $\frac{dx}{dt} + y = \sin t$ ;  $\frac{dy}{dt} + x = \cos t$

(i.e)

$$Dx + y = \sin t; \quad \dots(1)$$

$$Dy + x = \cos t \quad \dots(2)$$

First we can eliminate  $x$  from (1) and (2)

$$(2) \times D \Rightarrow Dx + D^2y = D \cos t = -\sin t \quad \dots(3)$$

$$\begin{array}{r} Dx \cancel{+} y = \sin t \\ \underline{Dx \cancel{+} D^2y = -\sin t} \\ (1) - (3) \Rightarrow (-D^2 - 1)y = 2 \sin t \end{array}$$

(i.e)  $(D^2 - 1)y = 2 \sin t$ , this is a 2<sup>nd</sup> order differential equation in  $y$  with constant coefficients.

$$y = \text{C.F.} + \text{P.I.}$$

Now the auxiliary equation is

$$m^2 - 1 = 0$$

$$\Rightarrow m^2 = 1$$

$$\Rightarrow m^2 = \pm 1$$

$$\Rightarrow \text{C.F.} = Ae^t + Be^{-t}$$

$$\text{P.I.} = \frac{1}{D^2 - 1}(-2 \sin t) = \frac{-2}{-1 - 1} \sin t \text{ (Replace } D^2 \text{ by } -1)$$

$$= \frac{2}{2} \sin t = \sin t$$

$$\therefore y = Ae^t + Be^{-t} + \sin t \quad \dots(4)$$

To find the solution of  $x$ , first let us find  $Dy$  and substitute the value in (2)

$$Dy = D[Ae^t + Be^{-t} \sin t] = Ae^t - Be^{-t} + \cos t$$

$$\text{Now (2)} \Rightarrow Dy + x = \cos t$$

$$\Rightarrow x = \cos t - Dy$$

$$= \cos t - (Ae^t - Be^{-t} + \cos t)$$

$$= \cancel{\cos t} - Ae^t + Be^{-t} - \cancel{\cos t}$$

$$x = Be^{-t} - Ae^t \quad \dots(5)$$

To find the value of  $A$  and  $B$ , We can use the given conditions

$$\text{Given } x(0) = 2, y(0) = 0$$

$$(4) \Rightarrow y(0) = Ae^0 + Be^{-0} + \sin(0) \text{ Since } t = 0$$

$$0 = A + B$$

$$\Rightarrow B = -A$$

$$(5) \Rightarrow x(0) = Be^{-0} - Ae^0 [t = 0]$$

$$2 = B - A$$

$$2 = -A - A = -2A$$

$$\therefore A = -1$$

$$\Rightarrow B = 1$$

$\therefore$  The solutions are

$$x = e^{-t} + e^t = 2 \cosh t \quad \because \cos ht = \frac{e^t + e^{-t}}{2}$$

$$y = e^{-t} - e^t + \sin t$$

$$= -(e^t - e^{-t}) + \sin t \quad \because \sin ht = \frac{e^t - e^{-t}}{2}$$

$$y = -2 \sinh t + \sin t$$

3. Solve  $Dx + y = \cos t$ ;  $x + Dy = 2 \sin t$ .

Solution: Given

$$Dx + y = \cos t; \quad \dots(1)$$

$$x + Dy = 2 \sin t \quad \dots(2)$$

$$\text{where } D = \frac{d}{dt}$$

First we can eliminate  $y$  from (1) & (2)

$$(1) \times D \Rightarrow D^2 x + Dy = D(\cos t) = -\sin t$$

(i.e)

$$D^2 x + \cancel{Dy} = -\sin t \dots\dots\dots(3)$$

$$\underline{x + \cancel{Dy} = 2 \sin t}$$

$$(3) - (2) \Rightarrow (D^2 - 1)x = -3 \sin t \dots\dots\dots(I)$$

which is a 2<sup>nd</sup> order differential equation in  $x$  with constant coefficients the solution of

$$x(t) = C.F. + P.I.$$

Now Auxiliary equation is

$$m^2 - 1 = 0$$

$$\Rightarrow m^2 = 1$$

$$\Rightarrow m = \pm 1$$

$$\therefore \text{C.F.} = Ae^t + Be^{-t}$$

$$\text{P.I.} = \frac{1}{D^2 - 1}(-3 \sin t)$$

$$= \frac{-3}{-1 - 1} \sin t \quad \text{Replace } D^2 \text{ by } -1$$

$$= \frac{3}{2} \sin t$$

$$\therefore x(t) = Ae^t + Be^{-t} + \frac{3}{2} \sin t \quad \dots(4)$$

Now to find  $y$  we can find  $Dx$  and then substitute  $Dx$  in (1).

$$Dx = D \left[ Ae^t + Be^{-t} + \frac{3}{2} \sin t \right]$$

$$= Ae^t - Be^{-t} + \frac{3}{2} \cos t$$

$$(1) \Rightarrow Dx + y = \cos t$$

$$\therefore y = \cos t - Dx$$

$$= \cos t - \left[ Ae^t - Be^{-t} + \frac{3}{2} \cos t \right]$$

$$= \cos t - Ae^t - Be^{-t} - \frac{3}{2} \cos t$$

$$= \frac{\cos t}{2} - Ae^t + Be^{-t}$$

$$y = Be^{-t} - \frac{\cos t}{2} - Ae^t$$

**Aliter**

To find  $y$  we can eliminate  $x$  from (1) & (2)

$$(2) \times D \Rightarrow Dx + D^2 y = D(2 \sin t) = 2 \cos t$$

$$(6) - (1) \Rightarrow Dx + D^2 y = 2 \cos t \dots\dots\dots(6)$$

$$Dx \cancel{+} y = \cos t$$

---

$$(D^2 - 1)y = \cos t \dots\dots\dots(\text{II})$$

$$\therefore y = CF + PI$$

Auxiliary equation is

$$m^2 - 1 = 0$$

$$m^2 = 1$$

$$m = \pm 1$$

$$\text{C.F.} = Ce^t + De^{-t}$$

[Since already  $A, B$  are introduced in  $x$ ]

$$\text{P.I.} = \frac{1}{D^2 - 1} \cos t$$

$$= \frac{1}{-1 - 1} \cos t \text{ Replace } D^2 \text{ by } -1$$

$$= \frac{-1}{2} \cos t$$

$$\therefore y(t) = Ce^t + De^{-t} - \frac{1}{2} \cos t \dots\dots(7)$$

Here the solutions of  $x$  and  $y$  contains four constants. But the solutions for  $x$  and  $y$  should contain as the order of equations (I) and (II).

Hence the values of  $C$  and  $D$  should be expressed interms of  $A$  and  $B$  as explained below.

Inserting the values of  $x$  and  $y$  in (1)

$$(i.e) \quad Dx + y = \cos t \quad \left[ \text{Here } Dx = \frac{d}{dt}(x) \right]$$

$$D \left[ Ae^t + Be^{-t} + \frac{3}{2} \sin t \right] + Ce^t + De^{-t} - \frac{1}{2} \cos t = \cos t$$

$$(i.e) \quad \frac{d}{dt} \left[ Ae^t + Be^{-t} + \frac{3}{2} \sin t \right] + Ce^t + De^{-t} - \frac{1}{2} \cos t = \cos t$$

$$Ae^t - Be^{-t} + \frac{3}{2} \cos t + Ce^t + De^{-t} - \frac{1}{2} \cos t - \cos t = 0$$

$$\Rightarrow Ae^t + Be^{-t} + \cancel{\frac{3}{2} \cos t} + Ce^t + De^{-t} - \cancel{\frac{3}{2} \cos t} = 0$$

$$\Rightarrow Ae^t - Be^{-t} + Ce^t + De^{-t} = 0$$

$$(i.e) \quad (A + C)e^t + (D - B)e^{-t} = 0.$$

$$A + C = 0, D - B = 0$$

$$(i.e) \quad -A = +C; D = B$$

( $\therefore e^t, e^{-t}$  will not be zero)

$$\therefore \text{The solutions are } x = Ae^t + Be^{-t} + \frac{3}{2} \sin t$$

$$\text{In (7), But } C = -A, D = B \quad y = Ae^t + Be^{-t} - \frac{1}{2} \cos t$$

Where  $A$  and  $B$  are arbitrary constants.

4. Solve  $\frac{dx}{dt} - y = t; \quad \frac{dy}{dt} = t^2 - x$  (S.U 2008, 2012)

Solution: Given  $Dx - y = t$ ;  $Dy = t^2 - x$  where  $\frac{d}{dt} = D$

$$(ie) \therefore CF = e^{\frac{-3}{2}t} \left( A \cos \frac{\sqrt{15}}{2}t + B \sin \frac{\sqrt{15}}{2}t \right)$$

First we eliminate  $x$  from (1) and (2)

$$Dx + D^2y = \cancel{2t} \rightarrow (3)$$

$$(3) - (1) \Rightarrow D\cancel{x} - y = t \rightarrow (1)$$

---

$$(D^2 + 1)y = t$$

is a differential equation in  $y$  with constant coefficients.

$$\therefore y = CF + PI$$

Now the auxiliary equation is

12. Solve  $D^2x + y = \sin t$ ;  $D^2y + x = \cos t$

Solution: Given  $D^2x + y = \sin t \rightarrow (1)$

$$x + D^2y = \cos t \rightarrow (2)$$

First we can be eliminate  $x$  from (1) and (2)

$$(2) \times D^2 \Rightarrow D^2x + D^4y = D^2(\cos t) = D(-\sin t) = -\cos t$$

$$\cancel{D^2x} + D^4y = -\cos t \dots \dots \dots (3)$$

$$\cancel{D^2x} + y = \sin t \dots \dots \dots (1)$$

---

$$(3) - (1) \Rightarrow (D^4 - 1)y = \cos t - \sin t$$

is a differential equation in  $y$  with constant co-efficients.

$\therefore y = \text{C.F.} + \text{P.I.}$

Now the auxiliary equation is

$$m^4 - 1 = 0$$

$$(i.e) (m^2 + 1)(m^2 - 1) = 0$$

$$\Rightarrow m^2 = -1, m^2 = 1$$

$$\Rightarrow m = \pm i, m = \pm 1.$$

$$\therefore \text{C.F.} = C_1 e^t + C_2 e^{-t} + C_3 \cos t + C_4 \sin t$$

$$\begin{aligned} \text{P.I.} &= \frac{1}{D^4 - 1} (-\cos t - \sin t) \\ &= \frac{-1}{D^4 - 1} \cos t - \frac{1}{D^4 - 1} (\sin t) \\ &= \frac{t}{4D^3} \cos t - \frac{1}{4D^3} (\sin t) \\ &= \frac{t}{4} \int \left\{ \int (\int \cos t dt) dt \right\} dt - \frac{t}{4} \int \left\{ \int (\int \sin t dt) dt \right\} dt \\ &= \frac{t}{4} \int \left\{ \int \sin t dt \right\} dt - \frac{t}{4} \int \left\{ \int -\cos t dt \right\} dt \\ &= -\frac{t}{4} \int -\cos t dt - \frac{t}{4} \int -\sin t dt \\ &= +\frac{t}{4} \sin t - \frac{t}{4} \cos t = \frac{t}{4} (\sin t - \cos t) \end{aligned}$$

$$\therefore y = C_1 e^t + C_2 e^{-t} + C_3 \cos t + C_4 \sin t + \frac{t}{4} (\sin t - \cos t)$$

First we can find  $Dy = \frac{d}{dt}(y)$

$$Dy = C_1 e^t - C_2 e^{-t} + C_3 \sin t - C_4 \cos t + \frac{t}{4} (-\cos t - \sin t) + \frac{1}{4} (\sin t - \cos t)$$

$$\therefore D^2y = C_1 e^t + C_2 e^{-t} - C_3 \cos t - C_4 \sin t + \frac{t}{4}(-\sin t - \cos t)$$

$$+ \frac{1}{4}(-\cos t - \sin t) + \frac{1}{4}(-\cos t - \sin t)$$

$$\text{Now (2)} \Rightarrow x = \cos t - D^2 y$$

$$x = \cos t - \left[ C_1 e^t + C_2 e^{-t} - C_3 \cos t - C_4 \sin t + \frac{t}{4}(\cos t - \sin t) - \frac{2}{4}(\cos t + \sin t) \right]$$

$$= \cos t - C_1 e^t - C_2 e^{-t} + C_3 \cos t + C_4 \sin t - \frac{t}{4}(\cos t - \sin t) + \frac{1}{2} \cos t + \frac{1}{2} \sin t$$

$$= \frac{3}{2} \cos t + \frac{1}{2} \sin t - C_1 e^t - C_2 e^{-t} + C_3 \cos t + C_4 \sin t - \frac{t}{4}(\cos t - \sin t)$$

$\therefore$  The solutions are

$$x = -\frac{3}{2} \cos t + \frac{1}{2} \sin t - C_1 e^t - C_2 e^{-t} + C_3 \cos t + C_4 \sin t - \frac{t}{4}(\cos t - \sin t)$$

$$y = C_1 e^t + C_2 e^{-t} - C_3 \cos t - C_4 \sin t + \frac{t}{4}(\sin t - \cos t)$$

Where  $C_1, C_2, C_3$  and  $C_4$  are arbitrary constants.

## METHOD OF VARIATION OF PARAMETERS

This method is very useful in finding the general solution of the second order equation.

$$\frac{d^2 y}{dx^2} + a_1 \frac{dy}{dx} + a_2 y = X \text{ where } a_1, a_2 \text{ are constants and 'X' is a function of } x.$$

The complementary function is

$$\text{C.F.} = Af_1 + Bf_2$$

Where  $A, B$  are constants and  $f_1$  and  $f_2$  are functions of  $x$ . Then particular Integral,

$$P.I. = Pf_1 + Qf_2$$

$$\text{Where } P = -\int \frac{f_2 X}{f_1 f_2 - f_1' f_2'} dx, \quad Q = \int \frac{f_1 X}{f_1 f_2 - f_2' f_1'} dx$$

The complete solution is

$$y = Af_1 + Bf_2 + P.I.$$

$$1. \quad \text{Solve } \frac{d^2 y}{dx^2} + y = \sec x \text{ by using method of variation of parameters.}$$

$$\text{Solution: Given } \frac{d^2 y}{dx^2} + y = \sec x$$

$$\text{(i.e.) } (D^2 + 1)y = \sec x$$

The Auxiliary Equation is

$$m^2 + 1 = 0$$

$$m^2 = -1 \Rightarrow m = \pm i \text{ [imaginary roots]}$$

$$\therefore \text{C.F.} = A \cos x + B \sin x$$

Here  $f_1 = \cos x$ ;  $f_2 = \sin x$ ;

$$f_1' = -\sin x; f_2' = \cos x$$

$$f_1 f_2' - f_1' f_2 = \cos^2 x + \sin^2 x = 1$$

$$P.I. = P f_1 + Q f_2$$

where

$$\begin{aligned} P &= - \int \frac{f_2 X}{f_1 f_2' - f_1' f_2} dx \\ &= \int \frac{\sin x \cos ecx}{1} dx \quad [\because x = \cos ecx] \\ &= - \int \sin x \cdot \frac{1}{\sin x} dx \\ &= - \int dx \\ &= -x \end{aligned}$$
